Abstract

We present in this paper an initial investigation into the use of a metagrammar for explicitly sharing abstract grammatical specifications for the Vietnamese language. We first introduce the essential syntactic mechanisms of the Vietnamese language. We then show that the basic subcategorization frames of Vietnamese can be compactly represented by classes using the XMG formalism (eXtensible MetaGrammar). Finally, we report on the implementation the first metagrammar producing verbal elementary trees recognizing basic Vietnamese sentences.

1 Introduction

Metagrammars (MG) have recently emerged as a means to develop wide-coverage LTAG for well-studied languages like English, French and Italian (Candito, 1999; Kinyon, 2003). MGs help avoid redundancy and reduce the effort of grammar development by making use of common properties of LTAG elementary trees.

We present in this paper an initial investigation into the use of a metagrammar for explicitly sharing abstract grammatical specifications for the Vietnamese language. We use the eXtensible MetaGrammar (XMG) tool which was developed by Crabbé (Crabbé, 2005; Parmentier and L. Roux, 2005) to compile a TAG for Vietnamese. The built grammar is called vnMG and is made available online for free access.

Only in recent years have Vietnamese researchers begun to be involved in the domain of natural language processing in general and in the task of parsing Vietnamese in particular. No work on formalizing Vietnamese grammar is reported before (Nguyen et al., 2004). In (Lê et al., 2006), basic declarative structures and complement clauses of Vietnamese sentences have been modeled using about thirty elementary trees, representing as many subcategorization frames. We show in this paper that these basic subcategorization frames can be compactly represented by classes in XMG formalism.

We first introduce the essential syntactic mechanisms of the Vietnamese language. We then show that the basic subcategorization frames of Vietnamese can be compactly represented by classes using the XMG formalism. We then report on the implementation the first metagrammar producing verbal elementary trees recognizing basic Vietnamese sentences, before concluding.

2 Vietnamese Subcategorizations

As for other isolating languages, the most important syntactic information source in Vietnamese is word order. The basic word order is Subject – Verb – Object. A verb is always placed after the subject in both predicative and question forms. In a noun phrase, the main noun precedes the adjectives and the genitive follows the governing noun. The other syntactic means are function words, reduplication, and, in the case of spoken language, prosody (Nguyễn et al., 2006).

From the point of view of functional grammar, the syntactic structure of Vietnamese follows a topic-oriented structure. It belongs to the topic-prominent languages as described by (Li and Thompson, 1976). In those languages, topics are
coded in the surface structure and they tend to control co-referentiality. The topic-oriented “double subject” construction is a basic sentence type. For example, “Cậu ấy khoẻ mạnh, là sinh viên y khoa / He strong, be student medicine”, which means that “He is strong, he is medicine student”. In Vietnamese, passive voice and cleft subject sentences are rare or non-existent.

In general, Vietnamese predicates may be classified into three types depending on the need of a copula connecting them with their subjects in the declarative and negative forms (Nguyễn, 2004). Complex predicates can be constructed to form coordinated predicative structures starting from these basic types of predicates. We present briefly these three types of Vietnamese predicates in the following subsections.

2.1 First Type Predicates
The first type predicates are predicates which connect directly to their subjects without the need of a copula in both of the declarative and negative forms. For example

- Declarative form: Tôi đọc sách. / I am reading books.
- Negative form: Tôi không đọc sách. / I am not reading books.

These predicates are assumed by verbal phrases or adjectival phrases. The fact that an adjective can be a predicate is a specificity of Vietnamese in comparison with predicates of occidental languages. In English or French for instance, only verbal phrases can be predicates, adjectives in these languages always signify properties of subjects and they are always followed the verb “to be” in English or “être” in French.

2.2 Second Type Predicates
The second type predicates are predicates which are connected to their subjects by the copula “là” in the declarative form and by copulas “không là” or “không phải”, or “không phải là” in the negative form. Predicates of this type are rather rich. They can be:

- Nouns or noun phrases: Tôi là sinh viên. / I am student.
- Verbs, adjectives, verbal phrases or adjectival phrases: Ván xin là yếu đuối. / Begging is feeble., Học cũng là làm việc / To study is to work.

2.3 Third Type Predicates
The third type predicates are predicates which connect directly to their subjects in the declarative form; however in the negative form, they are connected to their subjects by a copula. Predicates of this type are usually

- A clause: Nó vẫn tên là Quý. / His name is still Quý.
- A composition of a numeral and a noun: Lê này mười ngàn đồng. / This pear costs ten thousand dongs.
- A composition of a preposition and a noun: Lúa này của chị Hoa. / This is the rice of Ms. Hoa.
- An expression: Thằng ấy đầu bò đầu bướu lắm. / That guy is very stubborn.

2.4 Subcategorizations
In the first grammar LTAG for Vietnamese presented in (Lê et al., 2006), each subcategorization is represented by the same structure of elementary trees associated with a considered predicate. We view that the subject is subcategorized in the same way like arguments. The verbs anchor thus elementary trees composed of a node for the subject and one or more nodes for each of its essential complements.

We follow the de facto standard that in TAG, in which each subcategorization is represented by a family of elementary trees. We define families of verbal elementary trees in the Table 1.

We present in the next section a metagrammar that generates this set of elementary trees.

3 A Metagrammar for Verbal Trees
The subcategorizations of elementary trees describe only “canonical” constructions of predicative elements without taking into account for relative or question structures. For the purpose of investigation, we constraint ourselves in developing at the first stage only the verb spines and argument realizations shown in the subcategorizations presented in the previous section.

We have developed a XMG metagrammar that consists of 11 classes (or tree fragments). The

</tbody>
</table>

This paper presents an initial investigation into the use of XMG formalism for developing a first metagrammar producing a LTAG for Vietnamese which recognizes basic verbal constructions. We have shown that the essential subcategorization frames of Vietnamese predicates can be effectively encoded by means of XMG classes while retaining basic properties of the realized verbal trees. This confirms that various syntactic phenomena of Vietnamese can be covered in a Vietnamese MG.

The first evaluation of the MG for Vietnamese is promising but the lexical coverage has to be improved further. Moreover, the grammar coverage needs to be revised by refining the constraints of agrammatical syntactic constructions. Although there are not many tree fragments in the current metagrammar, we find that the current MG overgenerates some undesired structures. The MG will also be extended to deal with constructions not yet covered like adjectival and noun phrase constructions. We also intend to generate a test suite to document the grammars and perform realistic evaluations.

This metagrammar is currently able to produce the same set of elementary trees described in Table 1 including intransitive, transitive, ditransitive families with and/or without optional complements. As an illustration, the declarative transitive structure in Figure 1 can be defined by combining a canonical subject fragment with an active verb and a canonical object fragment.

```
S + S + S
   \  /   \  /
  N  |   V   \ __/
   \ |     \   /
     V     V  N
```

This combination is conveniently expressed by a statement in terms of XMG language as usual:

TransitiveVerb = Subject $\land$ ActiveVerb $\land$ Object.
